
Algorithm 3: Hierarchical Clustering and Averaging Regression

1. Apply hierarchical clustering of the genes to yield the nested correlation structure. We define $\mathcal{G}_s = (\mathcal{G}_1^s, \dots, \mathcal{G}_g^s, \dots, \mathcal{G}_{G_s}^s)$ a group partition in G_s groups and $\mathbf{X}_{\mathcal{G}_s}^s = [\mathbf{X}_{\mathcal{G}_1^s}^s, \dots, \mathbf{X}_{\mathcal{G}_{G_s}^s}^s]$ the concatenated matrix of variables for the partition \mathcal{G}^s .

2. for $s = 1, \dots, S$ do

 Create supergenes matrix $\tilde{\mathbf{X}}^s = \tilde{\mathbf{X}}_{\mathcal{G}_1^s}^s, \dots, \tilde{\mathbf{X}}_{\mathcal{G}_{G_s}^s}^s$ by averaging the gene expressions at each cluster of the current group partition \mathcal{G}^s :

$$\tilde{x}_{ig}^s = \frac{1}{G_s} \sum_{g \in \mathcal{G}_s} x_{ig}^s \quad \text{with } i = 1, \dots, n$$

 Fit Lasso, using the supergenes matrix $\tilde{\mathbf{X}}^s$ as input and retrieve the set of solution paths of the coefficients

end

3. Using cross-validation, find the optimal degree of shrinkage and level of the hierarchy.
